# ULI101 Week 05

## **Week Overview**

- Simple Filter Commands: head, tail, cut, sort, wc, grep, tr
- Redirection of Standard Input, Output, and Error
- Pipes and tee
- /dev/null File
- Here Documents

#### head and tail Commands

- These commands display the beginning or the end of a file respectively
- By default, 10 lines are displayed
  - The entire file will be displayed if it is less than 10 lines in length
- Example usage:

```
head [-line_count] file
for example: head -3 cars
for example: tail -3 cars
```

#### cut

- Selects which fields or columns to display from files or standard input
- Range can be specified in multiple ways:

```
    1-10 - first 10
    3-8 - 3<sup>rd</sup> to 8<sup>th</sup>
    - 10 - up to 10<sup>th</sup>
    - 2- - from 2<sup>nd</sup> until the end of line
    - 1-3,4,10- - combination of above
```

- Important options:
  - -c cut characters Example: cut -c1-2 - will cut first 2 characters
  - -f cut fields Example: cut -f2,5 - will cut 2<sup>nd</sup> and 5<sup>th</sup> field

## cut fields

- Default field delimiter is the tab
- Other field delimiter can be specified using the –d option
   For example:

```
cut-d, -f1-2 – will cut first 2 fields delimited with a comma
```

- Field delimiter must be a single character, only one character delimiters are supported
- If special characters are used for delimiters they must be quoted

For example:

```
cut -d" " -f1 - space is the field delimiter
```

## sort command

- Sorts files or standard input
- Is able to sort by fields
- Popular options:
  - -f fold (ignore case in comparisons)
  - -n numeric sort (default is ascii)
  - -u display unique entries only
  - (do not display duplicate lines)
  - -r reverse sort (default is lowest to highest value)

#### WC

- Counts the number of lines, words and/or characters in files or standard input
- Usage:

```
wc option [filename]
```

- Options:
  - count lines
  - w count words (delimited by whitespace)
  - c count bytes
  - m- count characters
  - If no option is specified, line, word, and byte counts are displayed
  - Note than one extended ascii character is one byte

## grep

- Searches for literal text and text patterns
  - Pattern-based searches will be covered in detail later in this course
- Example usage: grep ford cars
- Works with files or standard input
- Acts like a filter outputs only lines which are successfully matched to a given regular expression
  - A successful match can be an entire line or any part of it, but the entire line will be displayed

# **Useful grep options**

- -i ignores case
- -n numbers lines in the output
- -v reverse match
- -c displays count of matched lines

## **Standard Input and Standard Output**

- Standard input (stdin) is a term which describes from where a command receives input
- Standard output (stdout) describes where a command sends it's output
- For most commands the default standard input and output are your terminal's keyboard and screen
- Standard input can be redirected from a file or piped from another command
- Most commands also accept a filename argument, which is internally redirected to standard input
- Standard output can be redirected to a file or piped to another command

## **Standard Input Redirection**

command < filename

• Example:

```
tr 'a-z' 'A-Z' < cars
```

 Used for commands which do not accept a filename as an argument

## **Standard Output Redirection**

#### command > filename

- Redirects a command's standard output to a file
- Stdout redirection is represented by the > symbol Example:
  - ls > ls.txt will save output from the ls command into a file called ls.txt
- If the file exists already its content will be replaced
- To append (add) to a file, the >> symbol can be used

## **Standard Error**

- In addition to standard input and standard output UNIX commands have standard error, where error messages are sent
- By default error messages are sent to the terminal
- Standard error can be redirected by using the
   2> or 2>> redirection operators
- To redirect standard error to the same place as standard output, use 2>&1 redirection
- To redirect stdout to the same place as stderr, use >&2 redirection - this is how error messages are created in shell scripts

## **Pipes**

- Commands can send their standard output directly to standard input of other commands
- A few simple commands can be combined to form a more powerful command line
- No temporary files are necessary
- This is achieved by using pipes and tees

## **Pipes**

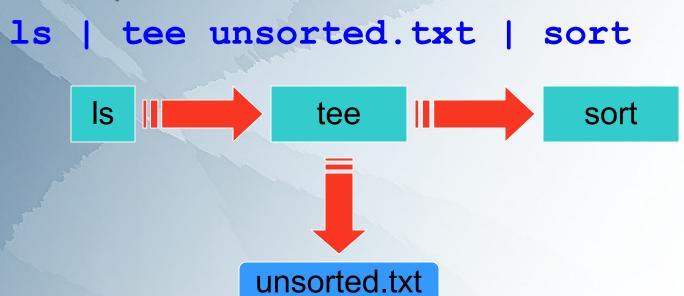

- Pipes are represented by
- Many commands can be "piped" together, filter commands are especially useful
  - Each filter processes the initial input based on it's design
  - Filters must be chained in a specific order, depending on what you wish to accomplish
- Example piping use:

```
1s -al | more
```

## Tee

 UNIX pipe with the tee utility can be used to split the flow of information

#### Example:

## /dev/null File

- The /dev/null file (sometimes called the bit bucket or black hole) is a special system file that discards all data written into it
  - Useful to discard unwanted command output, for example:
     find / -name "tempfile" 2> /dev/null
- Also, /dev/null can provide null data (EOF only) to processes reading from it
  - Useful to purge (empty) files etc, for example: cat /dev/null > ~/.bashrc

#### "Here" Documents

 The << symbol indicates a "here" document Example:

```
sort << EOF
```

word

name

car

EOF

- Anything between EOF...EOF is sent to the standard input of a utility
- You can use some other string instead of "EOF"
- This is especially useful for embedding a small file within a shell script
